Accepted 23 February 2014. Published Online 5 June 2014.

**Background** Information about the recurrence of spontaneous preterm birth in subsequent twin/singleton pregnancies is scattered.

**Objectives** To quantify the risk of recurrence of spontaneous preterm birth in different subtypes of subsequent pregnancies.

**Search strategy** An electronic literature search in OVID MEDLINE and EMBASE, complemented by PubMed, to find recent studies.

**Selection criteria** Studies comparing the risk of spontaneous preterm birth after a previous preterm and previous term pregnancy.

**Data collection and analysis** The absolute risk of recurrence with a 95% confidence interval and the absolute risk of preterm birth after a term delivery were calculated. Data from studies were pooled using the Mantel–Haenszel method.

**Main results** We detected 13 relevant studies. The risk of recurrence of preterm birth was significantly increased in all preterm pregnancy subtypes, compared with their term

counterparts. Women pregnant with twins after a previous preterm singleton had the highest absolute risk of recurrence (57.0%, 95% CI 51.9–61.9%), and after a previous term singleton their absolute risk was 25% (95% CI 24.3–26.5%). Women pregnant with a singleton after a previous preterm twin pregnancy have an absolute recurrence risk of 10% (95% CI 8.2–12.3%), whereas a singleton pregnancy after delivering a previous twin up to term yields a low absolute risk of only 1.3% (95% CI 0.8–2.2). Women pregnant with a singleton after a previous preterm singleton have an absolute recurrence risk of 20% (95% CI 19.9–20.6).

**Author's conclusions** The risk of recurrence of preterm birth is influenced by the singleton/twin order in both pregnancies, and varies between 10% for a singleton after previous preterm twins to 57% for twins after a previous preterm singleton.

**Keywords** Recurrence, singleton, spontaneous preterm birth, twin.

## Introduction

Preterm birth is one of the most widespread problems in obstetrics. In 2010, an estimated 14.9 million babies were born preterm, which was 11% of all live births worldwide.<sup>1</sup> Preterm birth and its complications are responsible for most neonatal deaths in otherwise healthy infants, and can lead to lifelong complications such as cerebral palsy, visual disorders and chronic diseases in adulthood.<sup>2,3</sup>

Recurrent spontaneous preterm birth is defined as more than one preterm birth related to the spontaneous onset of labour with intact membranes or preterm rupture of membranes.<sup>4</sup> Information about the risk of recurrence of preterm birth is important for women considering a subsequent pregnancy. In addition, obstetricians need these data to counsel women and to assess and apply preventive strategies.

Women with a twin pregnancy are known to be at increased risk of preterm birth, as around 40% will deliver spontaneously before 37 weeks of gestation.<sup>3</sup> Although

\*For a list of collaborators, see the Acknowledgements.

systematic reviews have been published on the biological background and treatment of recurrent preterm birth,<sup>4,5</sup> a clear overview of the magnitude of the risk of recurrent spontaneous preterm birth has so far not been available. We therefore decided to perform a systematic review of the risk of recurrence of spontaneous preterm birth in different subsequent pregnancy subtypes: women with a singleton pregnancy after a preterm singleton birth; women with a twin pregnancy after a preterm singleton birth; and women with a singleton pregnancy after a preterm twin birth. We also collected data on the course of pregnancy after a previous term delivery of singletons and twins.

## Methods

### Literature search

A medical librarian (JL) performed a comprehensive literature search of the electronic databases MEDLINE (OVID, from 1948) and EMBASE (OVID, from 1980) to identify publications on the risk of recurrence of preterm birth in singleton and multiple pregnancies. In addition, PubMed was searched for publications ahead of print not yet included in OVID MEDLINE using only text words and the command 'publisher[sb]'. The latest search update was 8 January 2013. An initial pilot search in PubMed established that some relevant papers were missed if we searched for all concepts simultaneously. We therefore constructed a rather complex search as follows. The basis was (A) a broad search for preterm birth combined with (B) a methodological filter (for clinical trials, observational and epidemiological studies, registries, medical history, etc.), using a strategy incorporating subject headings [e.g. Medical Subject Headings (MeSH) terms in MEDLINE] and text words in the title and the abstract. (A) plus (B) were successively combined with (C), a text word search for risk of recurrence of preterm birth, OR (D), a text word search for prediction/risk of preterm birth (without recurrence), OR (E) a broad search (using both subject heading and text words) for singletons or multiple pregnancies combined with a search for recurrence or prediction/risks. (E) had little added value over (C) and (D). Thus, the final search had the structure (A and B) and (C or D or E; for the entire MEDLINE search, see Appendix S1). A similar search was constructed for EMBASE. No language restrictions were applied. We excluded animal studies by using double negation (i.e. in MEDLINE 'not animals/not humans'). The search included an iterative process to refine the search strategy through adding search terms as new relevant citations were identified (i.e. by checking the reference lists of relevant papers). The bibliographic records retrieved were downloaded and imported into REFERENCE MANAGER<sup>®</sup> 12.0 (Thomson Reuters, Carlsbad, CA, USA) to remove duplicates, and to store and analyse the search results.

### Criteria for inclusion

#### Study design

We considered all cohort studies concerning the recurrence of spontaneous preterm birth for inclusion. Study size was not used as a limiting criterion for inclusion.

#### Study population

To be included, studies were required to include women with at least one spontaneous preterm birth at <37 weeks of gestation in their history or women with at least one term birth in their history. No limitations in relation to age, race, parity, the number of fetuses per pregnancy, or other baseline characteristics were set. Study populations consisting of only women with iatrogenic preterm birth or studies mixing both populations were excluded. Also, study populations consisting of other groups at high risk of preterm birth such as women with uterine anomalies and those who had had a previous abortion or cervical surgery without a previous preterm birth were excluded.

#### Outcome measures

Any of the following outcome measures were accepted for inclusion.

- 1 Risk of spontaneous preterm singleton delivery before 37 weeks of gestation after a preterm or term singleton delivery.
- 2 Risk of spontaneous preterm singleton delivery before 37 weeks of gestation after a preterm or term twin delivery.
- 3 Risk of spontaneous preterm twin delivery before 37 weeks of gestation after a preterm or term singleton delivery.

### Data extraction and quality assessment

Two authors (BK and PB) independently screened the titles and abstracts of identified studies. Relevant articles were selected and full texts were studied. Studies were selected by inclusion criteria and data extraction. Disagreements were resolved by consensus. Studies with data on the recurrence risk of preterm birth in a subsequent delivery were selected for further reading.

Data extraction was completed by BK and PB using a data extraction form. We did not contact authors for additional data. We determined the strength of the evidence using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) system.<sup>6</sup>

### Data analysis

The primary outcome was a recurrence of spontaneous preterm birth in a singleton birth after a previous singleton birth, in a twin birth after a previous singleton birth, or in a singleton birth after a previous twin birth before

37 weeks of gestation. A secondary outcome was the recurrence of preterm birth below other gestational age cut-offs. For each study, we constructed a table with the numbers of preterm and term births in the index pregnancy and the numbers of preterm and term births in subsequent pregnancies. For each study, we calculated the absolute risk of recurrence with a 95% confidence interval (95% CI) for the proportion of preterm births and the absolute risk of preterm birth after a term delivery, with a 95% CI.

Subsequently, data from the studies were pooled using the Mantel–Haenszel method. We converted odds ratios (ORs) or risk ratios (RRs) using the generic inverse variance method when no absolute numbers were available.<sup>7</sup> We chose to use a random-effects model because of the heterogeneity between the included studies. All analyses were performed with REVIEW MANAGER 5.1 (REVMAN; The Nordic Cochrane Centre, www.cochrane.dk; The Cochrane Collaboration, 2011).

## Results

The results of the search are shown in Figure 1. Our search identified 9104 publications (Appendix S1). Among these

were 2547 duplicates. We screened abstracts of the 6557 unique titles; 6519 of these were excluded because they did not match the inclusion criteria, whereas 39 articles were potentially relevant and therefore full texts of these articles were screened. Checking of cross-references did not reveal further studies. We excluded 26 further articles mainly because of the inability to extract absolute numbers, the lack of a control term group, or because they used (partly) the same population (see Appendix S2). When two articles described (partly) the same population, the largest most relevant publication was included in our systematic review.

Thirteen articles were relevant and included in this review: six studies on the risk of singleton–singleton subsequent births; four on twin–singleton subsequent births; and three on singleton–twin subsequent births.

### First singleton, second singleton

After applying the inclusion and exclusion criteria, six studies remained that described the risk of a spontaneous preterm singleton birth after a previous singleton pregnancy.<sup>8–13</sup>

Table 1 shows the characteristics of the included studies. The sample size of the included studies ranged from 1257 women (Mercer et al.<sup>12</sup>) to 452 680 women (Lykke

et al.<sup>11</sup>). We found that 22.1% [8056/(28 373 + 8056)] of all singleton preterm births in the second pregnancy were in women with a previous preterm singleton birth. The absolute risk of recurrence of a delivery before 37 weeks of gestation ranged from 15.8% in Lykke et al.<sup>11</sup> to 30.2% in Laughon et al.<sup>13</sup> (Figure 2). The pooled estimate of the absolute recurrence risk was 20.2% (95% CI 19.9–20.6%). The risk of a preterm singleton delivery before 37 weeks of gestation after a term singleton pregnancy ranged from 2.7% in Lykke et al.<sup>11</sup> to 7.6% in Mercer et al.<sup>12</sup> (pooled estimate 4.0%, 95% CI 3.9–4.0%; Figure 2).

Women with a previous singleton birth at <37 weeks of gestation were at a statistically significant increased risk for recurrent preterm birth compared with women with a previous term birth (pooled OR 5.43, 95% CI 4.03–7.31; Figure S1). Although three studies also did a subgroup analysis in groups delivering at other gestational ages, they all used different cut-off points. As a consequence, their results could not be pooled. They all individually showed an increasing risk of preterm birth with decreasing gestational age at first delivery.

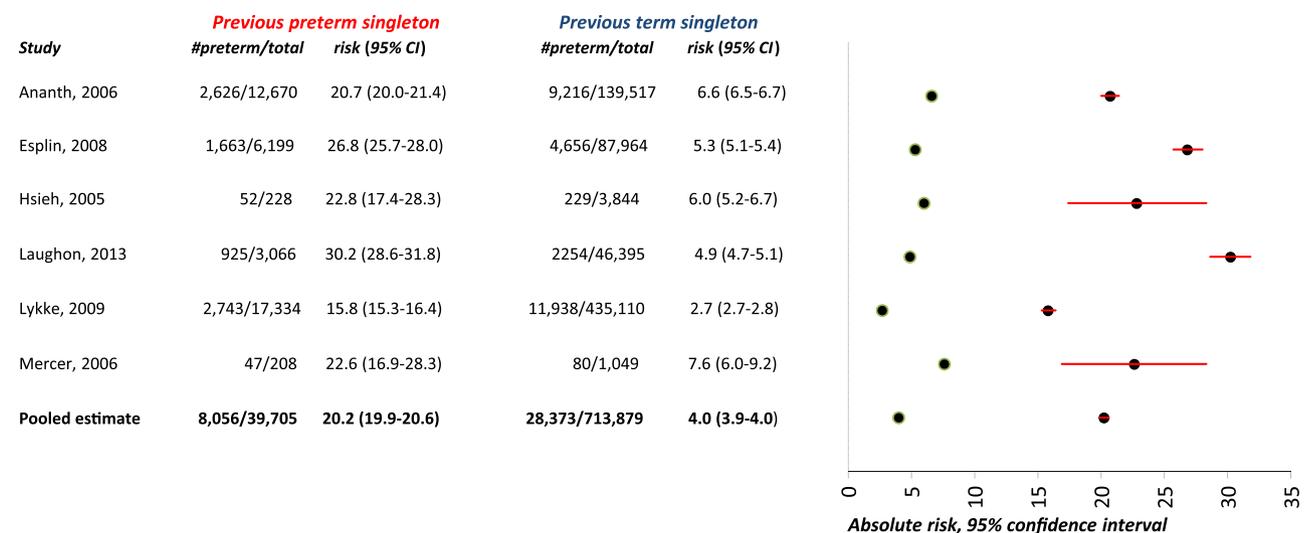

### First twin, second singleton

Four studies were identified that described the risk of a spontaneous preterm singleton birth after a previous twin pregnancy (Table 2).<sup>14–17</sup> We found that 84.4% [81/(81 + 15)] of all singleton preterm births in the second pregnancy were in women with a previous preterm twin birth. Both Rafael et al.<sup>16</sup> and Facco et al.<sup>14</sup> also included women with a term birth before the twin pregnancy. In contrast to the other studies, the study of Menard et al.<sup>15</sup> included mostly black women.

The risk of recurrent preterm birth ranged from 7.3% (Schaaf et al.<sup>17</sup>) to 19.8% (Menard et al.<sup>15</sup>; pooled estimate 10.0%, 95% CI 8.2–12.3%; Figure 3). The risk of a preterm singleton birth after a term twin birth ranged from 0.8% (Schaaf et al.<sup>17</sup>) to 6.9% (Menard et al.<sup>15</sup>; pooled estimate 1.3%, 95% CI 0.8–2.2%; Figure 3). Delivery of a preterm twin at <37 weeks of gestation was associated with a significantly increased risk of a spontaneous preterm birth in a subsequent singleton pregnancy, compared with the delivery of a previous term twin (pooled OR 6.7, 95% CI 2.3–19.1; Figure S2).

Three studies also described the risk of a subsequent preterm birth in a subgroup of twins delivered between 34 and 37 weeks of gestation.<sup>15–17</sup> They did not describe the absolute numbers of term and preterm births, so the absolute risk of recurrence could not be calculated; however, we were able to pool the risk ratios and odds ratios described in the individual studies. Delivery of a preterm twin between 34<sup>+0</sup> and 36<sup>+6</sup> weeks of gestation is associated with a significantly increased risk of a spontaneous preterm birth in a subsequent singleton pregnancy, compared with women who had delivered a previous twin at term (pooled OR 2.6, 95% CI 1.2–5.7; Figure S2).

Two studies also described the risk of a subsequent preterm birth for subgroups of a previous twin delivery between 30 and 34 weeks of gestation and below 30 weeks of gestation.<sup>15,17</sup> Rafael et al.<sup>16</sup> also subdivided data at lower gestational ages, but because they used different cut-off points their results could not be used in these pooled estimates. Delivery of a preterm twin between 30<sup>+0</sup> and 33<sup>+6</sup> weeks of gestation was associated with a significantly increased risk of spontaneous preterm birth in a subsequent singleton

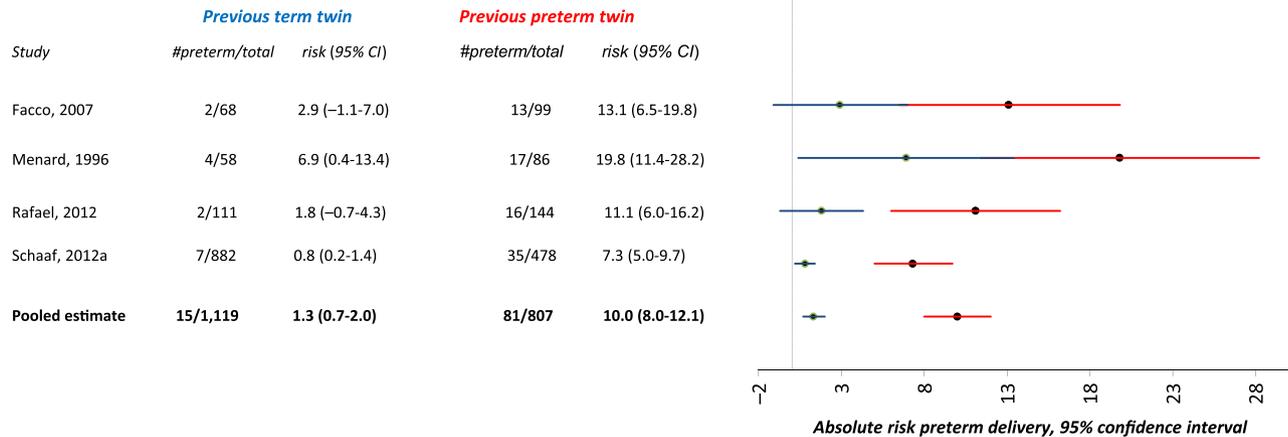

**Figure 2.** Absolute risk of singleton preterm birth after a previous term or preterm singleton birth.

Table 2. Characteristics of included studies: twin-singleton

First author	Year	Study type	Inclusion period	Setting	No. in study	Lost to follow-up/incomplete records	Lower limit PTD	Stillbirths in definition PTD	Inclusion criteria	Exclusion criteria	Mean age (years)	Race	Parity	Interpregnancy interval (months)
Facco <sup>14</sup>	2007	Cohort	1995–2005	Northwestern Memorial Hospital, Chicago, USA	167	9 (5%)	20 weeks	No	Women with a twin followed by a singleton pregnancy	Intrauterine death, major congenital anomalies, iatrogenic preterm births in either pregnancy, preterm delivery in history	PT 30.9, T 30.0	PT 69.7% white, T 70.6% white	PT 28.3%, T 30.9% previous term birth	NA
Rafael <sup>16</sup>	2012	Cohort	1996–2010	Christiana Care Health Systems, Newark, USA	255	0%	18 weeks	No	Women with a twin with a subsequent delivery in same hospital	Intrauterine death, major congenital anomalies, iatrogenic preterm births in either pregnancy, preterm delivery in history	PT 30.4, T 30.8	PT 68.1% white, T 61.3% white	PT 39.6%, T 41.4% previous term birth	PT 24.3%, T 15.3%, <6 or >60
Schaaf <sup>17</sup>	2012	Cohort	1999–2007	National Perinatal Registry, the Netherlands	1957	NA	22 weeks	No	Women with a first twin birth followed by a singleton pregnancy	Intrauterine death, major congenital anomalies, iatrogenic preterm births in the singleton pregnancy	PT 29.1, T 29.2	PT 88.7% white, T 91.4% white	Nulliparous women with two subsequent births	PT 33, T 36
Menard <sup>15</sup>	1995	Cohort	1981–93	Medical University of South Carolina, USA	144	NA	500 g	NA	Women delivering twins followed by a singleton pregnancy with prenatal care at university	Maternal transport, birthweights <500 g	25.2	85.4% black	NA	NA

NA, not available; PT, preterm singleton group; PTD, preterm delivery; T, term singleton group.

**Figure 3.** Absolute risk of singleton preterm birth after a previous term or preterm twin birth.

pregnancy (pooled OR 6.7, 95% CI 2.3–19.1; Figure S2). Delivery of a preterm twin at <30 weeks of gestation was associated with a significantly increased risk of spontaneous preterm birth in a subsequent singleton pregnancy (pooled OR 10.9, 95% CI 3.8–31.0; Figure S2).

### First singleton, second twin

We identified three eligible studies that estimated the risk of a spontaneous preterm twin after a singleton pregnancy (Table 3).<sup>18–20</sup> We found that 11.9% of preterm twins in the second pregnancy were in women with a previous preterm singleton.

The absolute risk of recurrence of spontaneous birth before 37 weeks of gestation varies within the studies from 47.5 to 73.9% (pooled estimate 57.0%, 95% CI 51.9–61.9%; Figure 4). The risk of a preterm twin after a term singleton pregnancy was 20.4% (Schaaf et al.<sup>20</sup>), 31.2% (Ananth et al.<sup>18</sup>), and 44.4% (Facco et al.<sup>19</sup>; pooled estimate 25.4%, 95% CI 24.3–26.5; Figure 4). A previous preterm singleton birth is associated with a significantly increased risk of a spontaneous preterm twin birth in a subsequent pregnancy, compared with a term singleton birth (pooled OR 3.8, 95% CI 1.4–10.7; Figure S3).

Although two studies (Ananth et al.<sup>18</sup> and Schaaf et al.<sup>20</sup>) performed subgroup analysis based on gestational age, they could not be pooled because of the different gestational age cut-offs used. Both studies found an increasing risk of preterm birth with a decreasing gestational age in the previous pregnancy.

### Quality of evidence

#### Study limitations

A majority of studies did not report on the completeness of data or loss to follow-up,<sup>8,10–12,15,17,18,20</sup> or did not even

describe exclusion criteria.<sup>8,9</sup> Also, some important baseline characteristics were not reported in studies, such as the race,<sup>10,11</sup> or parity,<sup>10,15</sup> of the women.

The lower limit for the definition of preterm birth differed between the included studies. Although most studies used 20 weeks of gestation as a lower limit,<sup>9,11–14,18,19</sup> 18 weeks of gestation,<sup>16</sup> 22 weeks of gestation,<sup>17,20</sup> or a weight cut-off were also used as lower limits.<sup>15</sup> Two studies did not mention a lower limit for preterm birth.<sup>8,10</sup> None of the studies including twins provided information about chorionicity.

#### Consistency

Inconsistencies were found in the comparison between singleton–singleton and singleton–twin, with  $I^2$  values of 99% ( $P < 0.001$ ) and 94% ( $P < 0.001$ ), respectively. These inconsistencies may be based on differences in baseline characteristics or the exclusion criteria of individual studies, but because of the lack of reporting in some studies this could not be proven. As a consequence, evidence was downgraded in these comparisons.

#### Directness

Most studies used women's first and second pregnancies to estimate the risks; however, some studies also included women with a previous term birth before the index pregnancy,<sup>12,14,16,19</sup> or any previous birth.<sup>13</sup> As a consequence, evidence was downgraded in these comparisons.

#### Precision

No important imprecision could be detected. Most studies were quite large, with narrow confidence intervals.

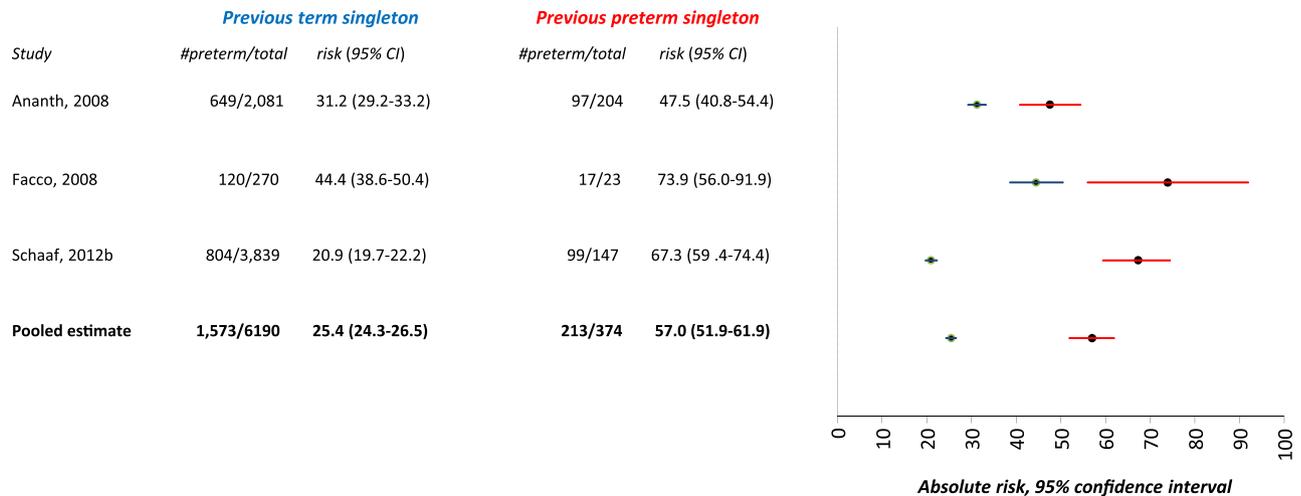

#### Publication bias

Publication bias cannot be completely ruled out, although both small and large studies were identified and included.

**Table 3.** Characteristics of included studies: singleton–twin

First author	Year	Study type	Inclusion period	Setting	No. in study	Lost to follow-up/incomplete records	Lower limit PTD	Stillbirths in definition PTD	Inclusion criteria	Exclusion criteria	Mean age (years)	Race	Parity	Interpregnancy interval (months)
Ananth <sup>18</sup>	2008	Cohort	1989–97	Retrospective cohort of births Missouri, USA	2329	NA	20 weeks	No	First singleton live birth followed by a gestation resulting in a twin live birth	Intrauterine death, no gestational age, or <20 weeks of gestation	32% 25–29	76.3% white	Nullipara with two subsequent pregnancies	30.6
Facco <sup>19</sup>	2008	Cohort	1995–2005	Northwestern Memorial Hospital, Chicago, USA	293	14 (4%)	20 weeks	No	Singleton birth followed by a twin birth at >20 weeks of gestation	iatrogenic PTD in singleton or twin, major anomaly, intrauterine death, prophylactic cerclage, women with prior preterm deliveries before study period	PT 32.2, T 31.5	PT 47.8% white, T 70.7% white	Prior term birth, PT 26.1%, T 21.8%	NA
Schaaf <sup>17</sup>	2012	Cohort	1999–2007	National Perinatal Registry, the Netherlands	4071	NA	22 weeks	No	First two pregnancies, singleton followed by a twin	iatrogenic PTD in subsequent twin pregnancy, major anomaly, intrauterine death	PT: 29.8, T 29.4	PT 94.4% white, T 91.9% white	Nullipara with two subsequent pregnancies	PT 28, T 28m

NA, not available; PT, preterm singleton group; PTD, preterm delivery; T, term singleton group.

**Figure 4.** Absolute risk of twin preterm birth after a previous term or preterm singleton birth.

### GRADE system

The quality of evidence according to the GRADE system is summarised in Tables S1–S3. As a consequence of downgrading for inconsistency and directness and upgrading for dose–response gradient, the overall quality of evidence for the singleton–singleton recurrence risk was judged to be very low (Table S1).

The overall quality for the twin–singleton recurrence risk and the subgroup 34<sup>+0</sup>–36<sup>+6</sup> weeks of gestation was judged to be low because of downgrading for directness and upgrading for dose–response gradient. The quality for the subgroups 30<sup>+0</sup>–33<sup>+6</sup> weeks of gestation and <30 weeks of gestation was judged to be moderate because of upgrading for the dose–response gradient (Table S2).

The singleton–twin comparison had some inconsistencies and problems with directness, leading to a very low overall level of quality (Table S3).

## Discussion

### Main findings

This systematic review provides an overview of the risk of recurrence of spontaneous preterm birth in different types of subsequent pregnancies. Recurrent preterm birth makes a substantial contribution to the total preterm birth count, with 22.1% of preterm singleton births occurring in women with a previous preterm singleton birth, with 84.4% of preterm singleton births occurring in women with a previous preterm twin birth, and with 11.9% of preterm twin births occurring in women with a previous preterm singleton birth. The risk of recurrence of spontaneous preterm birth is significantly increased in all pregnancy subtypes compared with their term counterparts. The strength of this

evidence is low to moderate for the twin–singleton comparison and very low for the singleton–singleton and singleton–twin comparisons. Women pregnant with a twin after a previous preterm singleton birth have the highest absolute risk of recurrence (57.0%), but even after a previous term singleton birth the absolute risk of preterm birth is still high (25.4%). Women pregnant with a singleton after a previous preterm twin birth have the lowest risk of recurrence (10.0%), and a pregnancy after a previous term twin birth yields the lowest absolute risk of preterm birth, at only 1.3%. Women pregnant with a singleton after a previous preterm singleton birth have an absolute risk of recurrence of 20.3%.

### Strengths and limitations

The strength of this systematic review is the relatively large sample sizes of the pooled estimates. The overall quality of the included studies was quite good; however, they were observational studies and as such are prone to several forms of bias. Limitations of the study design were taken into account in the assessment of the overall quality of the evidence.

Misclassification of preterm birth is an issue in all of the studies included in this review. If mentioned in the original publication, gestational age estimate was based on last menstrual period or on best clinical estimates. Ultrasound was only used in more recent years of the cohorts. Estimates of last menstrual period are known to be rather imprecise and could have led to the misclassification of preterm birth.<sup>21</sup> This could have led to women being classified as having had a previous preterm birth when it actually was a term birth, and to women being classified as having had a term birth when it was actually a preterm

birth.<sup>22,23</sup> The direction of this misclassification could be either way.

In addition, the lower limit for the definition of preterm birth differed between the included studies or was not even reported, making comparison difficult. Also, in the studies that reported on twins, no information about chorionicity was available. Finally, preterm stillbirths were excluded in almost all studies. Misclassification between stillbirth and live birth in very preterm babies is possible, which could also have influenced our results.

Although we were able to identify a lot of studies, various studies used different cut-offs for subgroup analyses at lower gestational ages. As a consequence these data could not be pooled, and not all of the existing evidence could be summarised in this review. Besides, some studies grouped spontaneous with indicated preterm birth, which meant that they were excluded from this review. Some studies on the subject were only published as conference abstracts, so more evidence is expected to be published in the future.

This systematic review was only limited to the risk of recurrence of spontaneous preterm birth because we think that the indications for iatrogenic preterm birth and the possible interchange between hypertensive disorders and growth restriction are very important for the specific risk of recurrence and also for counselling parents. This information is already available,<sup>24,25</sup> and is therefore outside the scope of this particular review. This decision could be doubted because there is evidence that women with a previous iatrogenic preterm birth are also at increased risk of a subsequent spontaneous preterm delivery.<sup>8,17,20,26</sup> In addition, most guidelines advise the induction of twins before 37 weeks of gestation, depending on the chorionicity of the twins. Women with an iatrogenic preterm birth might have delivered prematurely on their own for other reasons if there was no intervention. Excluding these women might have led to selection bias.

It is important to realise that the estimates in this review are only crude measures. Confounding factors may be responsible for some of the observed results. We were unable to correct for the confounding factors in each individual study. Furthermore, this review focused on only two successive pregnancies. The risk of recurrence might be different in women with more than one previous preterm birth.

Finally, information about possible treatments for the prevention of recurrent preterm birth was not available in the selected studies. It is possible that women with a previous preterm birth received treatment to prevent recurrence, such as progesterone, pessary, or cerclage. Treatment could have led to an underestimation of the absolute risk of recurrence.

## Interpretation

We now know that the risk of preterm birth is dependent not only on the gestational age of the previous pregnancy but also on the type of the previous and current pregnancy (twin or singleton). We can provide doctors and patients with more specific risks of recurrence based on specific obstetric history and the type of the current pregnancy.

We realise, however, that obstetric history in itself is not totally predictive of recurrent spontaneous preterm birth, but it is one of the factors available to counsel women before they start their second pregnancy. Once women are pregnant, we can further define their personal risk profile by adding cervical length measurement or certain biomarkers.<sup>27</sup>

## Conclusion

Although our review provides an overview, more detailed information is necessary for a better prediction of risk for individuals and for a better allocation of resources. We were unable to stratify on maternal race, for example, although differences in preterm birth rates between races have been shown before.<sup>1,28</sup> We therefore think that subdivision at the level of maternal race will be valuable. Similarly, stratification for the start of delivery (spontaneous labour versus premature rupture of membranes) and subdivisions for different weeks of gestation could be helpful, as decreasing gestational age is associated with increasing mortality, morbidity, and increased neonatal care and costs.<sup>1</sup>

In order to obtain these more individualised risk scores, other studies should be carried out. We did not attempt to obtain the original data from each study, although meta-analysis with individual patient data would be more accurate and would allow the creation of prediction models. We think that a global collaborative approach could be the solution to obtaining a more detailed risk scale, stratified for race, gender, and gestational age of delivery, in first and second pregnancies.

Our results underline the impact of recurrent preterm birth on the total preterm birth count, and indicate which women are most and which are least at risk of preterm birth, based on their obstetric history. It is clear that the risks of recurrence differ between different pregnancy subtypes. These risk estimations can be used to adjust the care for each specific risk group, evaluate innovative strategies for the prevention of recurrence or inform women about their risks in a subsequent pregnancy.

## Disclosure of interests

None of the authors have a conflict of interest.

## Contributions to authorship

BM and BK conceived this study. CL conducted the search. BK and PB analysed the data. BK wrote the first draft of the article. LM, CG, and BM supervised the data analysis and provided important intellectual content. All authors approved the final version of the article for publication.

## Funding

BK is a PhD student supported by a scholarship of the Academic Medical Centre graduate school. The authors received funding from the European Union made available to the EBM-CONNECT Collaboration through its Seventh Framework Programme, Marie Curie Actions, International Staff Exchange Scheme (proposal no. 101377; grant agreement no. 247613); EBM-CONNECT Canadian Collaborators received funding from the Canadian Institutes of Health Research. No funders were involved in the design and conduct of the study, in the collection, management, analysis, and interpretation of the data, or in the preparation, review, or approval of the article.

## Acknowledgements

The EBM-CONNECT (Evidence-Based Medicine Collaboration: Network for Systematic Reviews and Guideline Development Research and Dissemination) Collaboration (in alphabetical order by country) includes: L. Mignini, Centro Rosarino de Estudios Perinatales, Argentina; P. von Dadelszen, L. Magee, D. Sawchuck, University of British Columbia, Canada; E. Gao, Shanghai Institute of Planned Parenthood Research, China; B.W. Mol, K. Oude Rengerink, Academic Medical Centre, the Netherlands; J. Zamora, Ramon y Cajal, Spain; C. Fox, J. Daniels, University of Birmingham, UK; and K.S. Khan, S. Thangaratnam, C. Meads, Barts and the London School of Medicine, Queen Mary University of London, UK.

## Supporting Information

Additional Supporting Information may be found in the online version of this article:

**Table S1.** Grade evidence profile table for women pregnant with a singleton pregnancy after a preterm singleton delivery.

**Table S2.** Grade evidence profile table for women pregnant with a singleton pregnancy after a preterm twin delivery.

**Table S3.** Grade evidence profile table for women pregnant with a twin pregnancy after a preterm singleton delivery.

**Figure S1.** Risk of preterm singleton birth at <37 weeks of gestation after a previous spontaneous preterm singleton delivery at <37 weeks of gestation.

**Figure S2.** Risk of a preterm singleton delivery at <37 weeks of gestation after a previous spontaneous preterm twin birth at <37 weeks of gestation, at 34<sup>+0</sup>–36<sup>+6</sup> weeks of gestation, at 30<sup>+0</sup>–33<sup>+6</sup> weeks of gestation, and at <30 weeks of gestation.

**Figure S3.** Risk of preterm singleton delivery at <37 weeks of gestation after a previous preterm twin birth at <37 weeks of gestation.

**Appendix S1.** Search strategy.

**Appendix S2.** References of studies excluded after screening of full text, as described in Figure 1. ■
